

Python Notes - Days 1 to 3

Summary of our lessons.

Day 1

print() displays output. Variables store values, e.g. name='Abhijeet'.

Day 2

input() gets user input and ALWAYS returns a string. Strings are text inside quotes. '10'+'20' becomes '1020'.

Day 3

Data types: str=text, int=whole numbers, float=decimal numbers. type() checks a value's type. int() converts numeric strings to integers.

Operators

+ - * / // % **. Division (/) returns a float. // removes the decimal part. % gives the remainder. ** means power.

Calculator

Use int(input()) for numbers, then perform +, -, *, /, // and %.
